

# 6.5 Exercise: Bootstrap re-sampling (VITonline version)

This exercise will enable you to use <u>VITonline</u> to construct a Bootstrap Confidence Interval for a single numeric and a single categorical variable.

VIT is a developing collection of software modules for use in exploring core concepts involved in drawing conclusions from data.

### The skills addressed are:

Use VITonline to generate a bootstrap distribution and confidence interval.

### **INSTRUCTIONS**

Start <u>VITonline</u> and select the <u>Bootstrapping</u> option.

Load the NHANES-1000-50 data set from Example Data (not NHANES-1000). [Your data set should have only 50 rows.]

We will use our sample of 50 people to form a Bootstrap Confidence interval for the mean **BMI** of the NHANES-1000 data which we looked at in Week 5 exercises.

In the variable list, click on **BMI** and then click the **Analyse** button (under the variable list).

You will see the BMI values for 49 people in our sample plotted on a graph with a box plot below it. (One person had a missing value for BMI).

- Under Statistic, select mean (this is the default)
- Click Precalculate Display

Next, make your selections in the middle part of the window under **Resampling**.

- Select 1 repetition
- Click Go.

You will see a re-sample of size 49 from the original sample being selected in red.

What is happening in the graphics window?

A plot of the **Re-sample** will appear in the middle part of the graphics window.

Do the same thing selecting 5 repetitions

Now we'll use the bottom part of the **Analyse** window that says **Bootstrap Distribution**.

Select 5 repetitions and click Go.

This will generate 5 re-samples of size 49 and the mean of each re-sample will be calculated and be shown by a blue line in the **Re-sampling** plot. A disc will be generated from the mean of each re-sample and will drop down into the **Bootstrap distribution** plot.

The above plot shows 5 re-samples have been taken so far because there are 5 circles in the **Bootstrap distribution** plot.

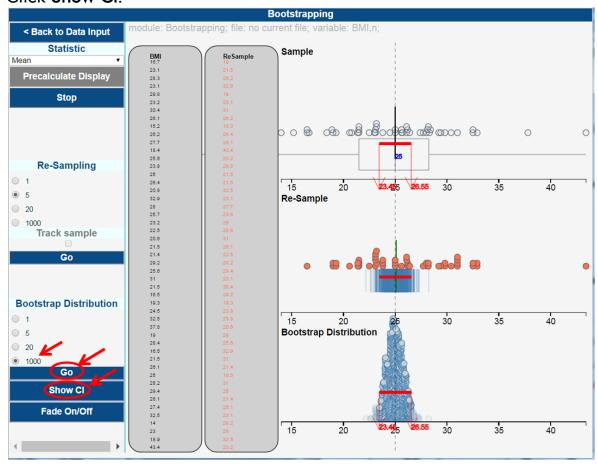

In the bottom part of the Analyse window (Bootstrap Distribution)

• Select 1000 repetitions click Go.

You will see a **bootstrap distribution** of the means of 1000 re-samples taken from the initial sample of size 49.

# Get the Bootstrap Confidence Interval

• Click Show Cl.

# What is happening in the graphics window?

The **Bootstrap distribution** is a build-up of 1000 re-sample means and shows the variation between re-sample means.

The Bootstrap Confidence Interval has trimmed off the bottom and top  $2 \frac{1}{2}$ % of the re-sample means and appears in red (23.45, 26.55). This interval will appear on the two plots above as well.

The resulting interval is the values within which we are fairly sure that the mean BMI value for the NHANES-1000 population lies.

Note that your values will probably be slightly different.

# EXPLORE (~5 min)

What other numeric variables can you form a bootstrap confidence interval for using your sample of 50 NHANES participants? How do your results compare with the sampling variations in the previous week?

Post a comment about anything interesting you have found.

# Construct a Bootstrap Confidence Interval for a categorical outcome (proportion)

Now, use the sample of size 49 to generate a bootstrap distribution for estimating the proportion of people in the NHANES-1000 population who are classified as obese (BMI over 30) using the variable BMI\_WHO (levels of BMI as decided by the World Health Organisation).

Under the Use test data tab

Select variable BMI\_WHO

- At the bottom of the left-hand panel see Choose Category to focus on and select 30.0\_plus
- Click on Analyse

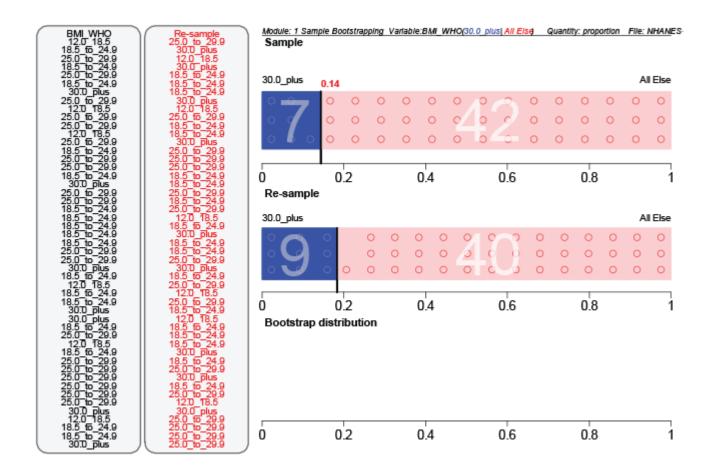

From here everything behaves as before.

• Click on Precalculate Display

Under the **Re-sampling** section

- Select 1
- Click Go.

## Example Data CanadaPop.csv Census at School-500.csv /lindsetMatters.csv JHANES-1000-50.csv IHANES-1000.csv Use test data SurveyYr (c) ID (n) Gender (c) Age (n) AgeDecade (c) Race3 (c) Education (c) MaritalStatus (c) HHIncome (c) HHIncomeMid (n) Poverty (n) HomeRooms (n) HomeOwn (c) Work (c) Weight (n) Height (n) BMI (n) BMI\_WHO(c) Pulse (n) BPSysAve (n)

# What is happening in the graphics window?

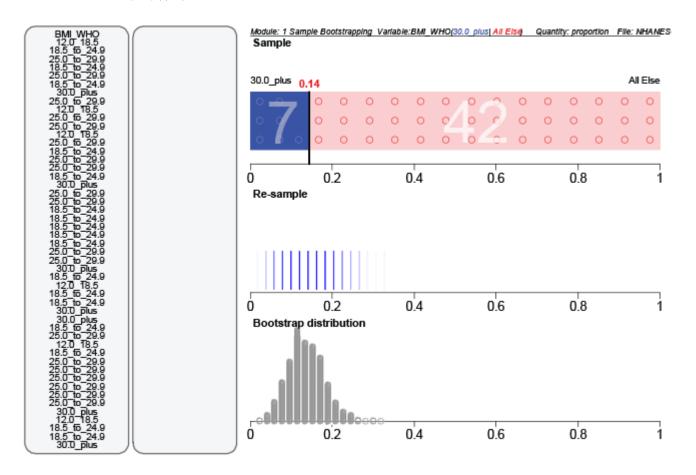

The original sample has 49 values. A re-sample of size 49 is being taken from the original sample.

# Under the Bootstrap Distribution section

- Select 1000
- Click Go.

Once the 1000 re-samples have been selected and the bootstrap distribution completed:

Select Show Cl.

What proportion of participants in the NHANES-1000 population do we expect to be classified as "Obese"?

# EXPLORE (~5 min)

What other numeric or categorical variables can you form a bootstrap confidence interval for using your sample of 50 NHANES participants? How do your results compare with the sampling variations in the previous week?

Post a comment about anything interesting you have found.

# Common questions

### What does CI mean?

CI stands for Confidence Interval. If you click the **Show CI** button, a 95% bootstrap confidence interval will show on the plots.

# What is Fade on/off?

You can only click **Fade on/off** after you have put a confidence interval on your plots. Then the re-sampling and bootstrap distributions will fade and you'll be left with your initial estimated proportion from your initial sample with a 95% bootstrap confidence interval superimposed on it. Fading may not work if you have resized your plotting window.

### Do I have to do the animation?

No. The animation is there for you to see how each re-sample is selected from
